Network Flow (Cont.)

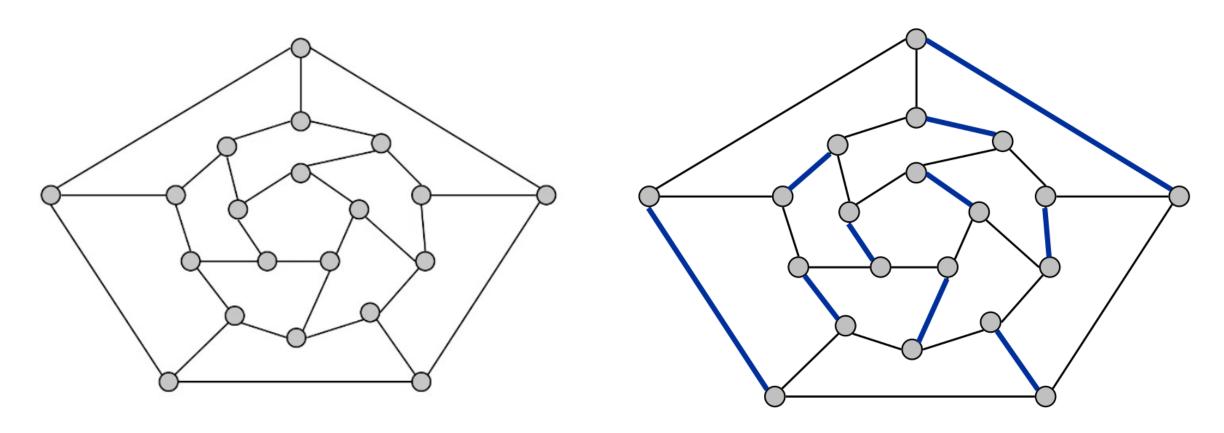

Quan Li Fall 2023 2023.10.31

Matching

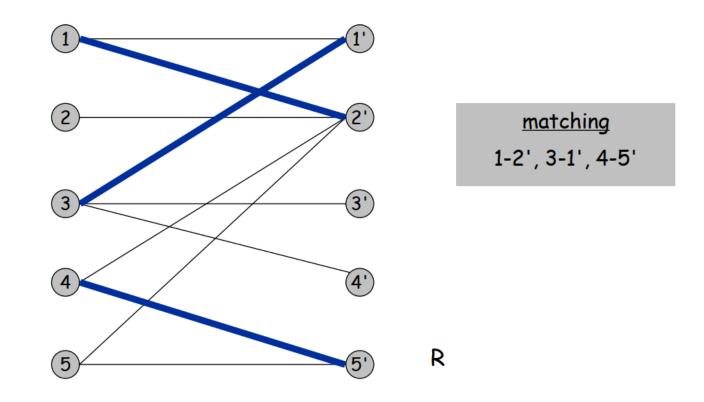

Matching

- Input: undirected graph G = (V, E)
- $M \subseteq E$ is a matching if each node appears in at most one edge in M
- Max matching: find a max cardinality matching

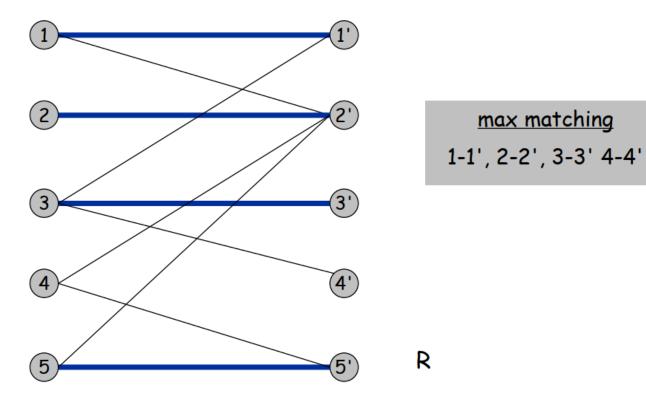

- Bipartite matching
 - Input: undirected, bipartite graph $G = (L \cup R, E)$
 - $M \subseteq E$ is a matching if each node appears in at most one edge in M
 - · Max matching: find a max cardinality matching

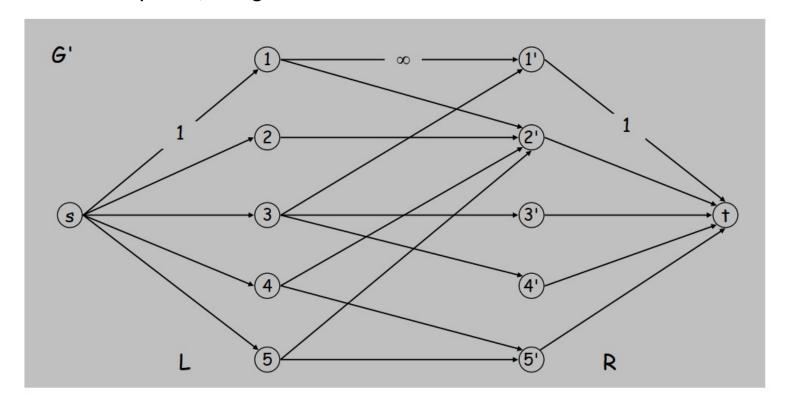

- Bipartite matching
 - Input: undirected, bipartite graph $G = (L \cup R, E)$
 - $M \subseteq E$ is a matching if each node appears in at most one edge in M
 - · Max matching: find a max cardinality matching

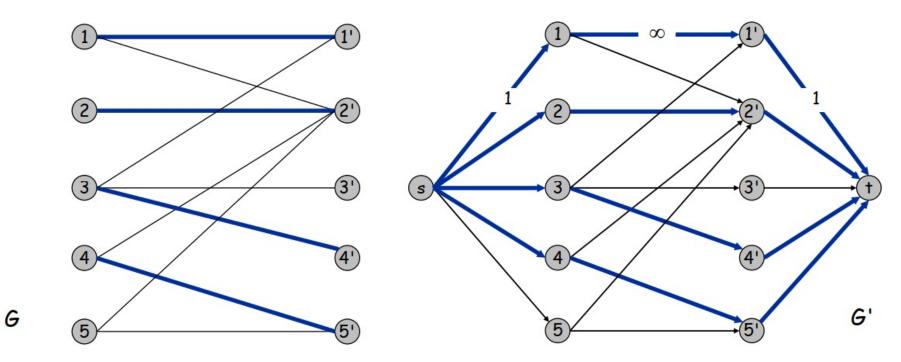

Max flow formulation

- Create digraph $G' = (LURU\{s, t\}, E')$
- Direct all edges from L to R, and assign infinite (or unit) capacity
- · Add source s, and unit capacity edges from s to each node in L
- Add sink t, and unit capacity edges from each node in R to t

Bipartite Matching: Proof of Correctness

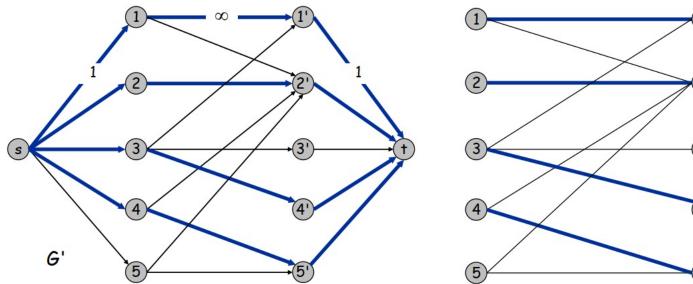

- Theorem. Max cardinality matching in G = value of max flow in G'
- Pf. <=
 - Given max matching M of cardinality k
 - Consider flow f that sends 1 unit along each of k paths
 - f is a flow, and has cardinality k

Bipartite Matching: Proof of Correctness

- Theorem. Max cardinality matching in G = value of max flow in G'
- Pf. >=
 - Let f be a max flow in G' of value k
 - Integrality theorem \rightarrow k is integral and can assume f is 0-1
 - Consider M = set of edges from L to R with f(e) = 1
 - Each node in L and R participates in at most one edge in M
 - |M| = k: consider cut (LUs, RUt)

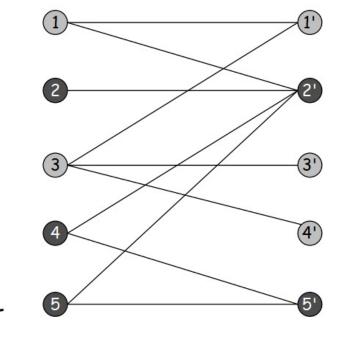

Perfect Matching

- Def. A matching $M \subseteq E$ is perfect if each node appears in exactly one edge in M
- Q. When does a bipartite graph have a perfect matching?
- Structure of bipartite graphs with perfect matchings
 - Clearly we must have |L| = |R|
 - What other conditions are necessary?
 - What conditions are sufficient?

ŧ,

Perfect Matching

- Notation. Let S be a subset of nodes, and let N(S) be the set of nodes adjacent to nodes in S
- Observation. If a bipartite graph $G = (L \cup R, E)$, has a perfect matching, then |N(S)| >= |S| for all subsets $S \subseteq L$
- Pf. Each node in S has to be matched to a different node in N(S)

No perfect matching:

$$S = \{2, 4, 5\}$$

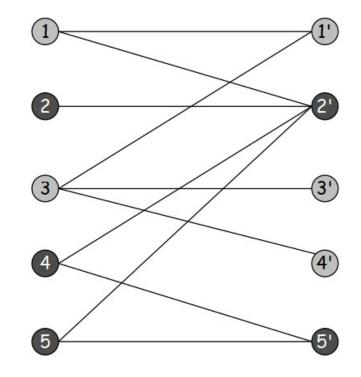

$$N(S) = \{ 2', 5' \}.$$

Marriage Theorem

• Marriage Theorem. [Frobenius 1917, Hall 1935] Let $G = (L \cup R, E)$ be a bipartite graph with |L| = |R|. Then, G has a perfect matching iff |N(S)| >= |S| for all subsets $S \subseteq L$

• Pf. → This was the previous observation

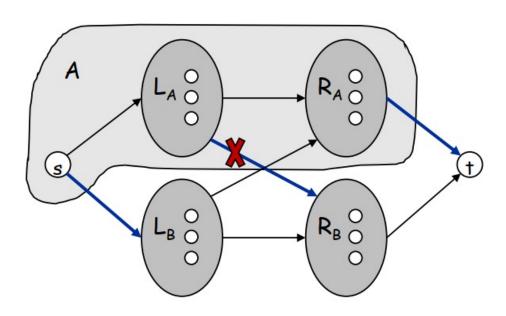

No perfect matching:

$$S = \{2, 4, 5\}$$

$$N(5) = \{ 2', 5' \}.$$

Proof of Marriage Theorem

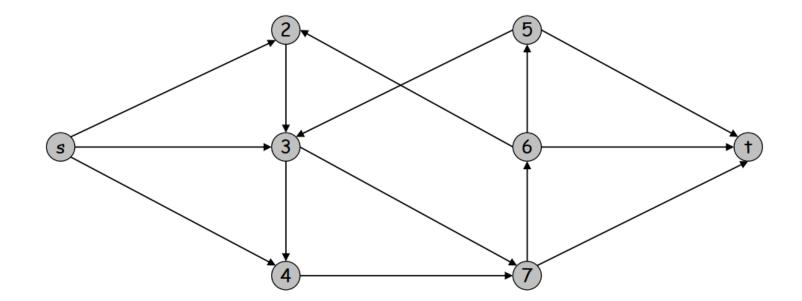

- Marriage Theorem. G has a perfect matching iff |N(S)| >= |S| for all subsets S ⊆ L
- Pf. ← Suppose G does not have a perfect matching
 - Formulate as a max flow problem and let (A, B) be min cut in G'
 - Define $L_A = L \cap A$, $L_B = L \cap B$, $R_A = R \cap A$, $R_B = R \cap B$
 - $Cap(A, B) = v(f^*) = |M| < |L| ("<": because no perfect matching)$
 - Since min cut can't use ∞ edges, no edge between L_A and R_B
 - $Cap(A, B) = |L_B| + |R_A|$
 - $N(L_A) \subseteq R_A$
 - $|N(L_A)| <= |R_A|$ = $cap(A, B) - |L_B|$ $< |L| - |L_B|$ $= |L_A|$
 - This contradicts the condition

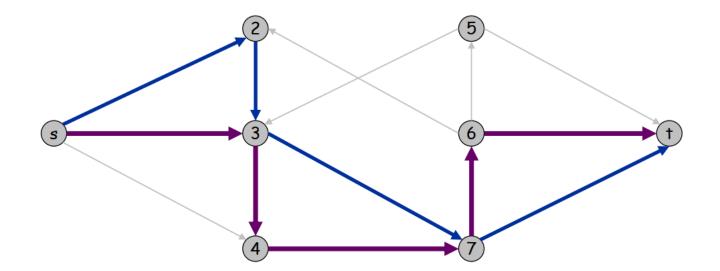

Disjoint Paths

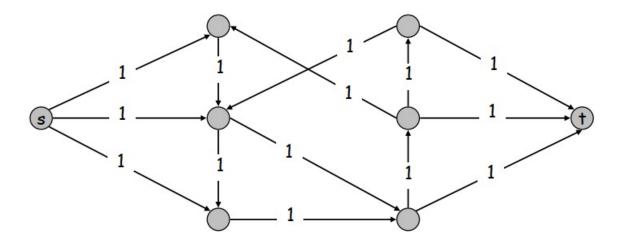

- Disjoint path problem. Given a digraph G = (V, E) and two nodes s and t, find the max number of edge-disjoint s-t paths
- Def. Two paths are edge-disjoint if they have no edge in common
- Ex: communication networks

- Disjoint path problem. Given a digraph G = (V, E) and two nodes s and t, find the max number of edge-disjoint s-t paths
- Def. Two paths are edge-disjoint if they have no edge in common
- Ex: communication networks

• Max flow formulation: assign unit capacity to every edge

• Theorem. Max number edge-disjoint s-t paths equals to max flow value

- Theorem. Max number edge-disjoint s-t paths equals max flow value
- Pf. <=
 - Suppose there are k edge-disjoint paths P_1 , ..., P_k
 - Set f(e) = 1 if e participates in some path P_i ; else set f(e) = 0
 - Since paths are edge-disjoint, f is a flow of value k

- Theorem. Max number edge-disjoint s-t paths equals max flow value
- Pf. >=
- Suppose max flow value is k
- Integrality theorem → there exists 0-1 flow f of value k
- Consider edge (s, u) with f(s, u) = 1
 - By conservation, there exists an edge (u, v) with f(u, v) = 1
 - Continue until reach t, always choosing a new edge
 - So we get a s-t path
- Reduce the flow to 0 along the path, so we get a flow of value k-1
- Repeat the process for k times, then we get k (not necessarily simple) edge-disjoint paths

Can eliminate cycles to get simple paths if desired

Extensions to Max Flow

- Circulation with demands
 - Directed graph G = (V, E)
 - Edge capacities c(e), e ∈ E
 - Node supply and demands d(v), v ∈ V

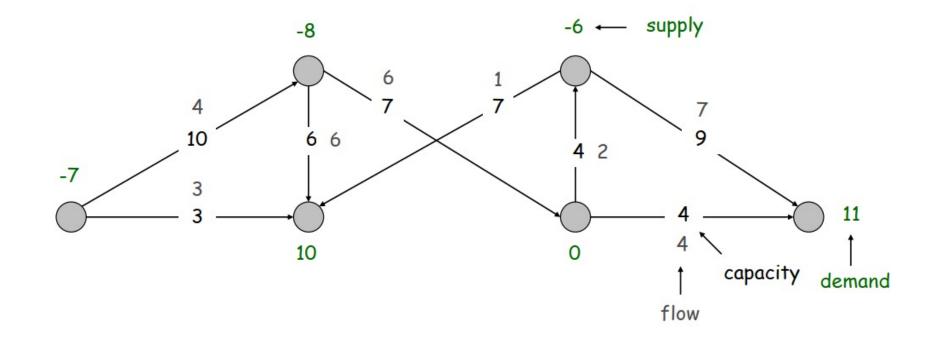

demand if d(v) > 0; supply if d(v) < 0; transshipment if d(v) = 0

- **Def.** A circulation is a function that satisfies:
 - For each $e \in E$: 0 <= f(e) <= c(e) (capacity)
 - For each $v \in V$: $\sum f(e) \sum f(e) = d(v)$ (conservation)
- Circulation problem: given (V, E, c, d), does there exist a circulation?

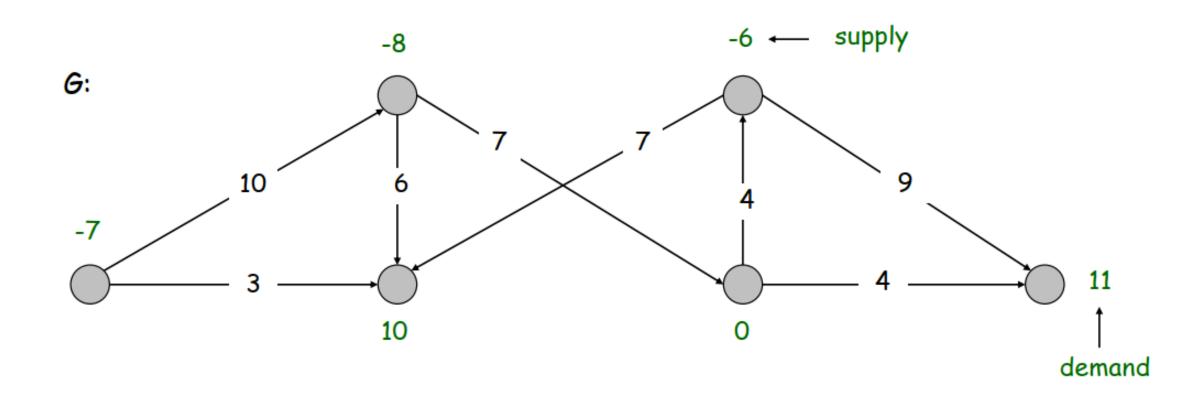

• Necessary condition: sum of supplies = sum of demands

$$\sum_{v:d(v)>0} d(v) = \sum_{v:d(v)<0} -d(v) =: D$$

• Pf. Sum conservation constraints for every demand node v

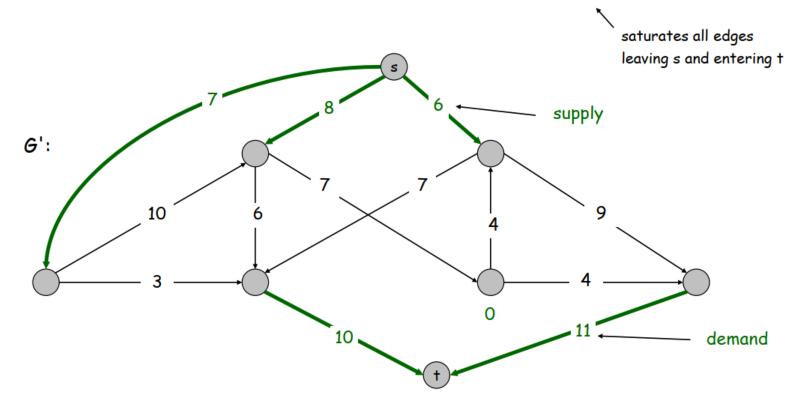

Max flow formulation

Max flow formulation

- Add new source s and sink t
- For each v with d(v) < 0, add edge (s, v) with capacity -d(v)
- For each v with d(v) > 0, add edge (v, t) with capacity d(v)
- · Claim. G has circulation iff G' has max flow of value D

- Integrality theorem. If all capacities and demands are integers, and there exists a circulation, then there exists one that is integer-valued
- Pf. Follows from max flow formulation and integrality theorem for max flow
- Characterization. Given (V, E, c, d), there does not exist a circulation iff there exists a node partition (A, B) such that $\sum_{v \in B} d_v > cap(A, B)$

demand by nodes in B exceeds supply of nodes in B plus max capacity of edges going from A to B

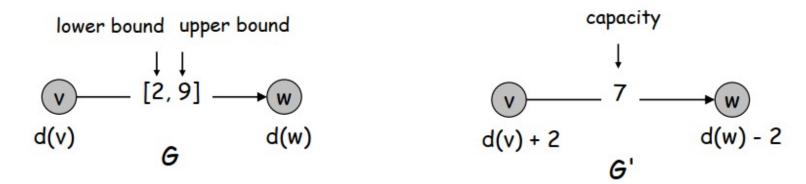

Pf idea. Look at max flow and min cut in G'

Circulation with Demands and Lower Bounds

- Feasible circulation
 - Directed graph G = (V, E)
 - Edge capacities c(e) and lower bounds ℓ (e), $e \in E$
 - Node supply and demands d(v), v ∈ V
- Def. A circulation is a function that satisfies:
 - For each $e \in E$: $\ell(e) \leftarrow f(e) \leftarrow c(e)$ (capacity)
 - For each $v \in V$: $\sum_{e \text{ in to } v} \frac{\sum f(e) \sum f(e)}{e \text{ out of } v} = d(v) \quad \text{(conservation)}$
- Circulation problem with lower bounds. Given (V, E, ℓ , c, d), does there exist a circulation?

Circulation with Demands and Lower Bounds

- Idea. Model lower bounds with demands
 - Send ℓ (e) units of flow along edge e
 - Update demands of both endpoints

- Theorem. There exists a circulation in G iff there exists a circulation in G'. If all demands, capacities, and lower bounds in G are integers, then there is a circulation in G that is integer-valued
- Pf sketch. f(e) is a circulation in G iff $f'(e) = f(e) \ell(e)$ is a circulation in G'

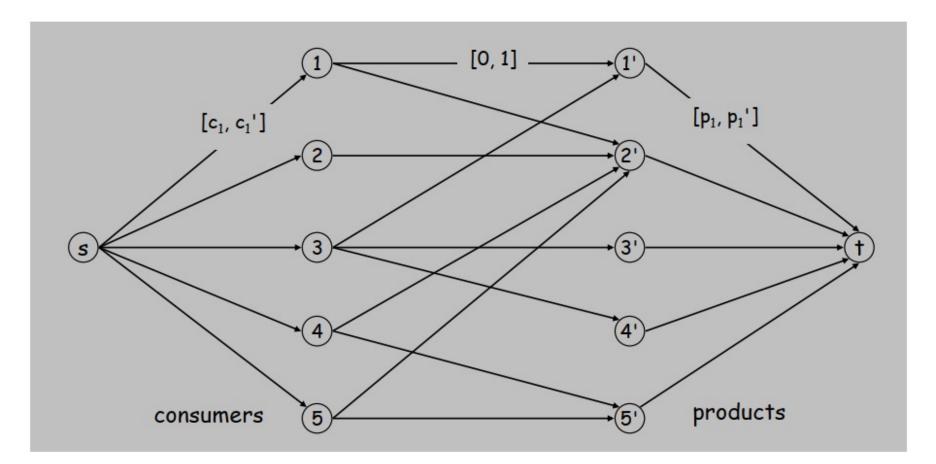

- Survey design
 - Design survey asking n₁ consumers about n₂ products
 - · Can only survey consumer i about a product j if they own it
 - Ask consumer i between c_i and c'_i questions
 - Ask between p_i and p'_i consumers about product j
- · Goal. Design a survey that meets these specs, if possible

- Algorithm. Formulate as a flow-network?
 - Include an edge (i, j) if customer own product i
 - Goal: find a flow that satisfies edge upper & lower bounds. How?

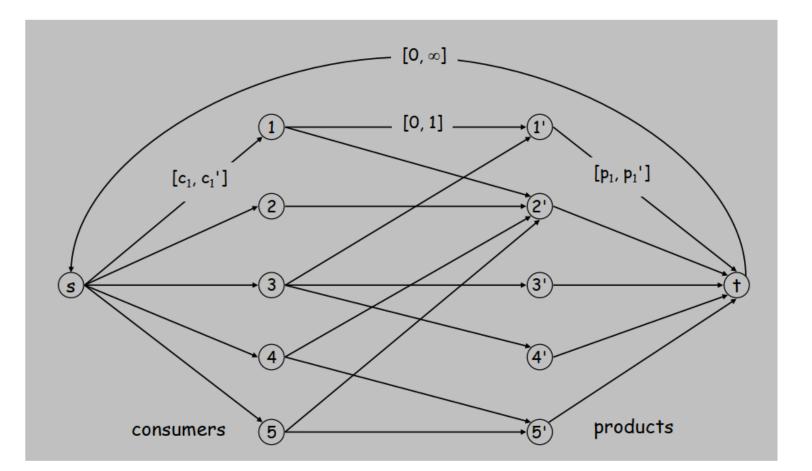

- Algorithm. Formulate as a circulation problem with lower bounds
 - Include an edge (i, j) if customer own product i
 - Integer circulation → feasible survey design

- Image segmentation
 - Central problem in image processing
 - Divide image into coherent regions
- Ex: Two people standing in front of complex background scene. Identify each person as a coherent object

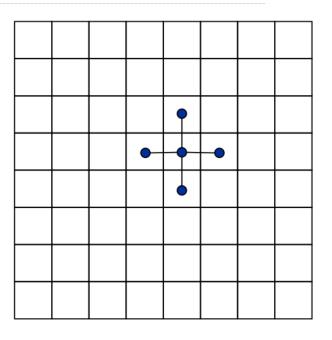

Foreground / Background segmentation

- Label each pixel in picture as belonging to foreground or background
- V = set of pixels, E = pairs of neighboring pixels
- a_i >= 0 is likelihood pixel i in foreground
- b_i >= 0 is likelihood pixel i in background
- $p_{ij} >= 0$ is separation penalty for labeling one of i and j as foreground, and the other as background

• Goals

- Accuracy: if a_i > b_i in isolation, prefer to label i in foreground
- Smoothness: if many neighbors of i are labeled foreground, we should be inclined to label i as foreground
- Find partition (A, B) that maximizes:

$$\begin{array}{ccc} \sum a_i + \sum b_j & - & \sum p_{ij} \\ i \in A & j \in B & & (i,j) \in E \\ & & |A \cap \{i,j\}| = 1 \end{array}$$

- Formulate as min cut problem
 - Maximization
 - No source or sink
 - Undirected graph
- Turn into minimization problem

is equivalent to minimizing
$$\underbrace{\left(\sum_{i \in V} a_i + \sum_{j \in V} b_j\right)}_{\text{a constant}} - \underbrace{\sum_{i \in A} a_i - \sum_{j \in B} b_j}_{i \in A} + \underbrace{\sum_{(i,j) \in E} p_{ij}}_{|A \cap \{i,j\}| = 1}$$

or alternatively

$$\sum_{j \in B} a_j + \sum_{i \in A} b_i + \sum_{(i,j) \in E} p_{ij}$$
$$|A \cap \{i,j\}| = 1$$

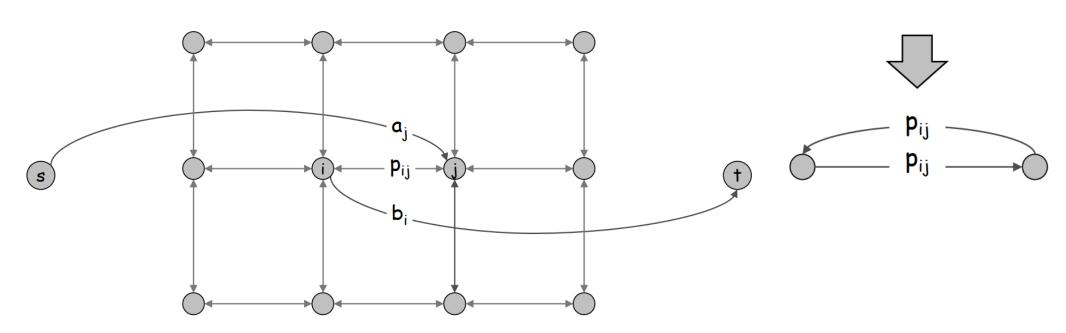

- Formulate as min cut problem
 - G' = (V', E')
 - · Add source to correspond to foreground; add sink to correspond to background
 - · Use two anti-parallel edges instead of undirected edge

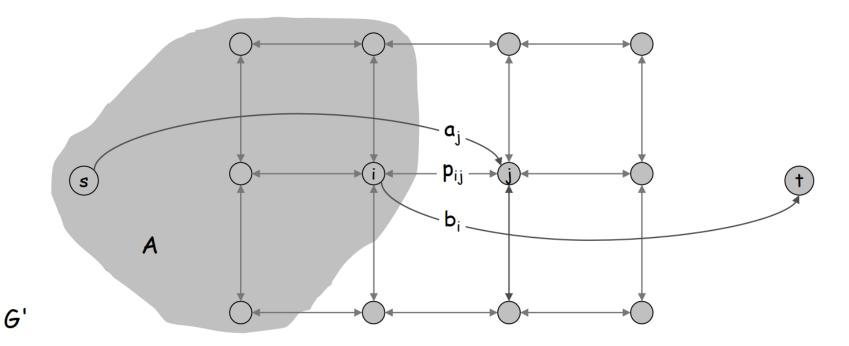

- · Consider min cut (A, B) in G'
- A = foreground

$$cap(A,B) \ = \ \sum_{j \in B} a_j + \sum_{i \in A} b_i \ + \sum_{\substack{(i,j) \in E \\ i \in A, \ j \in B}} p_{ij} \qquad \text{if i and j on different sides,} \\ p_{ij} \text{ counted exactly once}$$

• Precisely the quantity we want to minimize
